#### 1. Abstract

The project focusses on building 3D models from buildings' segmentation from satellite images. The software built for the project takes an image as input, predicts the segmentation using a machine learning model, followed by a series of image processing techniques to identify the contours and areas of the identified building segments. This information is carried on to create the 3D models.

#### 2. Aim

The aim is to create a project that allows to build 3D models from buildings' segmentation from satellite images.

### 3. Objective

The objective of the project is to create a software that would identify and build 3D models of buildings from an input image.

The objectives include the following:

- 1. Creating a CNN based machine learning model to predict the segmentation of buildings in the image
- 2. Create a flow of image processing steps on the intermediate results to prepare the contour information for the Unity module
- 3. Create the Unity module which uses this information to create 3D models

#### 4. Literature survey

### 4.1 [1] Satellite Image Classification for Detecting Unused Landscape using CNN

This paper contributes to the automation of the process of finding vacant land space. A is used in this work. It is a satellite image processing technology that discovers unused land. suggested. As the basis for this study, remote sensing earth photographs are used. dataset in which the preprocessing stage involves image conversion picture conversion to greyscale, compression, and noise removal Segmentation is used to divide a region into useful and unused areas. lands. Local binary feature extraction is used in this case.

Method for identifying edge, flat, and corner surfaces As The many algorithms listed above are utilized in categorization and remote sensing earth image labelling The CNN algorithm is also used. categorization is used, and classification labelling is completed automatically by the use of the CNN algorithm.

4.2 [2] Conjunction and synchronization methods of earth satellite images with local

cartographic data

There is a quick summary of interactive maps of the area and various perspectives, including

interactive maps with visualization. The most popular services in the area with interactive

maps, as well as their types and applications, are considered. The technique for processing

satellite photos and then placing them in cartographic services is provided.

Individual project fragments for editing interactive maps for various types of locations are

also offered. Orientation problems with greatest precision are discussed using the services

OpenStreetMap, Yandex. Maps, and Google Earth, as well as the benefits of using interactive

maps for different types of users.

4.3 [3] Satellite Image Analysis: A Review

A great deal of work has been done for satellite image analysis, which includes studies ranging

from classification of handcrafted characteristics for high performance computing using

satellite imagery The researchers have accomplished a lot. achievement in satellite image

analysis However, a systematic review,

It will help researchers to pinpoint the issue and to develop a solution There is a void in this

field. An example is given in the preceding chapter. An attempt has been made to offer a

comprehensive review of a variety of satellite image processing, classification, and analysis

steps databases that are available This chapter will provide impetus for additional study in this

subject and will serve as a baseline to investigation into satellite image processing.

5

### 5. Proposed Methodology

### **5.1 High Level Overview**

Modules Involved:

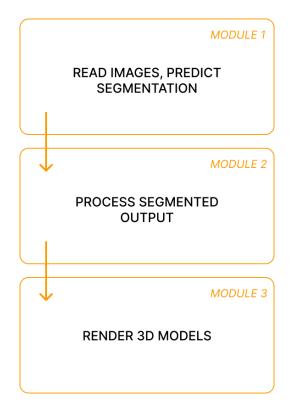

Fig 1 - Modules involved: High Level

### **5.2 Module Description:**

### **5.2.1 Segmentation Prediction using machine learning model**

This module uses a machine learning model to predict the segmentation of buildings in the input image.

The machine learning model is trained using a dataset obtained from Kaggle.

Table 3 – CNN Model Summary

Total params: 44,977

Trainable params: 44,645 Non-trainable params: 332 **5.2.1.3 Dataset** 

Link: https://www.kaggle.com/code/kmader/segmenting-buildings-in-satellite-images/data

Total number of images: 281,000

**5.2.2** Image processing on Segmentation

The segmented intermediate output image is processed through the following image processing

steps, as follows:

i. Bilateral Filter

ii. Color space transformation from BGR to GRAY

iii. Dilation

iv. Erosion

Canny Edge Detection v.

vi. Contour Detection

The bilateral filter is a non-linear, smoothing filter, that preserves edges in the image. The

intensity of each pixel is replaced with the weighted average of the intensity values of the

nearby pixels.

The *cv2.bilateralFilter()* is used for the above operation

The color space is converted from BGR to GRAY. The *cv2.cvtColor()* function is used for this

operation.

Dilation operation is performed to expand the image pixels, and adds pixels in the object

boundaries. The *cv2.dilate()* function is used for this operation.

Erosion operation is performed to remove the image pixels, and removes pixels from the object

boundaries. The *cv2.erode()* function is used for this operation.

10

Canny Edge detection is a multi-stage algorithm to detect a range of edges in images. The *cv2.Canny()* function is used for this operation.

Contours are curves joining all continuous points having the same color and intensity. Detecting these is termed contour detection. The *cv2.findContours()* and *cv2.contourArea()* function is used for this operation, and returning the area of the identified contours.

#### **5.2.3** Render 3D models

The information regarding the contours and the areas of the identified contours are used to render the 3D models. The information is stored in the local storage of the web browser, which is read from the jslib plugin file, which is used to communicate with the browser from the WebGL block.

Once the values are read, the Generator file would create 3D block prefabs of appropriate area as returned by the segmented outputs stored locally in the browser.

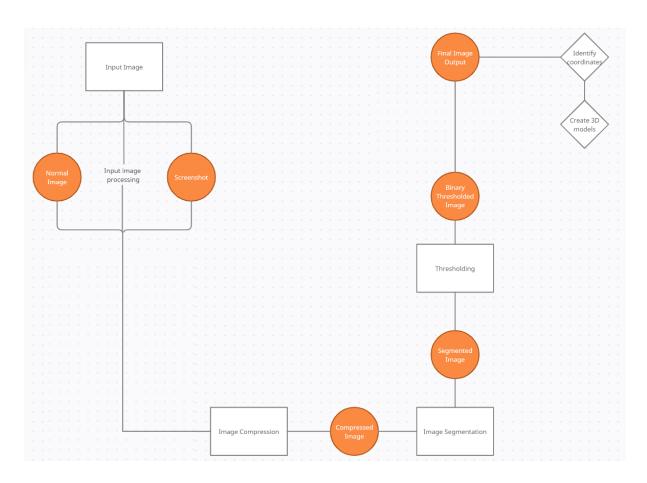

Fig 2 - Module 2: Process segmented output

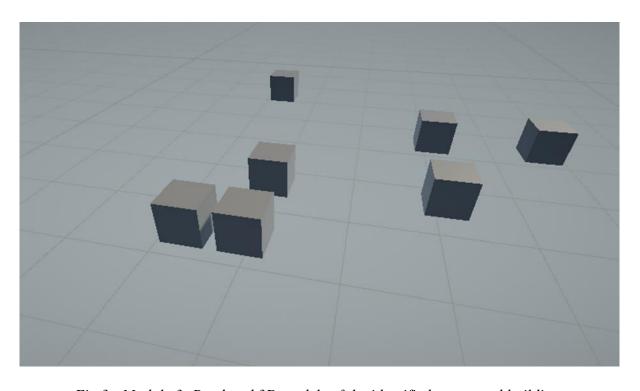

Fig 3 - Module 3: Rendered 3D models of the identified segmented buildings

The image input is taken, followed by compression. The compressed image is fed into a trained machine learning model. The machine learning model predicts the accurate segmentation for the buildings in the image. The segmentation is preformed followed by a thresholding operation. The threshold output is further processed in the following order.

vii. Bilateral Filter

viii. Color space transformation from BGR to GRAY

ix. Dilation

x. Erosion

xi. Canny Edge Detection

xii. Contour Detection

The output yields the image with contours marked as well as the areas of each identified contour. This information is now passed to the Unity module. The Unity module creates 3D blocks of the respective areas as returned by the previous module.

### 6. Results

The web application renders a 3D model of the segmented buildings in the input image
